

SOYA HULLS

PRODUCT DESCRIPTION

Soy hulls are a by-product of soybean processing from oil and meal production. Soy hulls consist primarily of the skin covering the soybean. Typically soy hulls do not need further processing to feed. The 'super' fibre in soy hulls is rapidly fermented, highly digestible and may contain substantial amounts of pectin, helping overall Rumen function.

Soy hulls are utilised in diets for dairy cattle as partial replacements for forage and concentrate. The fibre of soybean hulls is very digestible and coupled with a very low non-structural carbohydrate content the product is an excellent energy and fibre source. This results in a more favourable rumen fermentation pattern. Soy hulls come in a pellet form; however, due to the high fibre content the pellet is soft and you may see a higher meal content at time of delivery.

FEEDING RECOMMENDATIONS:

Soy hulls may be used without major restrictions in properly formulated beef and dairy rations. Soy hulls can be fed on the feed pad, via some feed systems in the shed or on a trailer, trough in the paddock. Using soybean hulls in energy-dense dairy rations especially high starch diets may improve animal performance. Consult your local WSF Representative to determine the optimal feeding level for your particular situation.

STORAGE AND HANDLING:

Like all feedstuffs, Soy hulls should be stored dry, in bulk bins or placed on cement slabs away from vermin and protected from the weather.

TYPICAL ANALYSIS: (approx.)

ME	10.5-11.0	MJ/KG/DM
Crude Protein	10.5-12.5	%
Dry Matter	90	%
Crude Fat	1.5-2.5	%
NDF	65	%
